Abstract

The relation between answer set programming (ASP) and propositional satisfiability (SAT) is at the center of many research papers, partly because of the tremendous performance boost of SAT solvers during last years. Various translations from ASP to SAT are known but the resulting SAT formula either includes many new variables or may have an unpractical size. There are also well known results showing a one-to-one correspondence between the answer sets of a logic program and the models of its completion. Unfortunately, these results only work for specific classes of problems.

In this paper we present a SAT-based decision procedure for answer set programming that \textit{(i)} deals with any (non disjunctive) logic program, \textit{(ii)} works on a SAT formula without additional variables, and \textit{(iii)} is guaranteed to work in polynomial space. Further, our procedure can be extended to compute all the answer sets still working in polynomial space. The experimental results of a prototypical implementation show that the approach can pay off sometimes by orders of magnitude.

Introduction

Propositional satisfiability (SAT) is one of the most studied fields in Artificial Intelligence and Computer Science. Also motivated by the availability of efficient SAT solvers various reductions from logic programs to SAT were introduced in the past.

Fages (1994) showed that if a program \( \Pi \) is “tight” then its answer sets (or stable models) are in one-to-one correspondence with the models of its completion (Clark 1978). If the completion is converted to a set of clauses \( \Gamma \), state-of-the-art SAT solvers can be used as answer set generators. Since the size of \( \Gamma \) is at most twice the size of \( \Pi \), and has at most \( m \) new variables (where \( m \) is the number of rules in the logic program) this is considered a viable and efficient approach. Fages’ result was then generalised to include programs with infinitely many rules (Lifschitz 1996), programs tight “on their completion model” (Babovich, Erdem, & Lifschitz 2000), and programs with nested expressions in the bodies of the rules (Erdem & Lifschitz 2003). Still these results do not apply to the whole class of logic programs. It is well known that each answer set corresponds to a model of its completion, but the viceversa in general is not true.

Ben-Eliyahu and Dechter (1996) gave a translation from a class of disjunctive logic programs to SAT. However the translation may need \( O(n^3) \) new variables and \( O(n^3) \) new clauses (where \( n \) is the number of atoms in the logic program). Janhunen (2003) presented an optimized encoding of this translation, which behaves subquadratic in both size and number of atoms.

A reduction to SAT which does not need extra variables was proposed by Lin and Zhao (2002). The drawback of this reduction is that the resulting formula may blow-up in space. Still system ASSAT based on such reduction outperforms state-of-the-art ASP systems likeSMODELS (Niemelä 1999; Simons 2000) and DLV (Eiter et al. 1998) on many interesting problems.

In this paper the question that we positively answer is: Is it possible to build an efficient SAT-based answer set generator that \textit{(i)} deals with any (non disjunctive) logic program, \textit{(ii)} works on a SAT formula without additional variables except for those eventually introduced by the clause form transformation, and \textit{(iii)} is guaranteed to work in polynomial space? We present a procedure, called ASP-SAT, having the above three but also other features. We integrated ASP-SAT in CMODELS\textsuperscript{1} and ran a wide comparative analysis with other state-of-the-art systems. The results show that our procedure has a clear edge over them.

The paper is structured as follows. First we introduce some necessary definitions and terminology. Second we present the main ideas behind our procedure and some details for an effective implementation. We end the paper describing the integration in CMODELS, the experimental results, and the conclusions.

Formal Background

Let \( P \) be a set of atoms. A \textit{rule} is an expression of the form

\[ A_0 \leftarrow A_1, \ldots, A_m, \text{not } A_{m+1}, \ldots, \text{not } A_n \]  

(1)

\textsuperscript{1}http://www.cs.utexas.edu/users/tag/cmodes
where $A_0 \in P \cup \{\bot\}$ ($\bot$ is the logical symbol standing for False), and $\{A_1, \ldots, A_n\} \subseteq P$ ($0 \leq m \leq n$). $A_0$ is the head of the rule, $A_1, \ldots, A_m$, not $A_{m+1}, \ldots, \text{not } A_n$ is the body. A (non disjunctive) logic program is a finite set of rules.

In order to give the definition of an answer set we consider first the special case in which the program $\Pi$ does not contain the negation as failure operator not (i.e., for each rule (1) in $\Pi$, $n = m$). Let $\Pi$ be such a program and let $X$ be a set of atoms. We say that $X$ is an answer set for $\Pi$ if $X$ is the smallest set closed under $\Pi$.

Now consider an arbitrary program $\Pi$. Let $X$ be a set of atoms. The reduct $\Pi^X$ of $\Pi$ relative to $X$ is the set of rules

$$A_0 \leftarrow A_1, \ldots, A_m$$

for all rules (1) in $\Pi$ such that $X \cap \{A_{m+1}, \ldots, A_n\} = \emptyset$. Thus $\Pi^X$ is a program without negation as failure. We say that $X$ is an answer set for $\Pi$ if $X$ is an answer set for $\Pi^X$.

Our next step is to introduce the relation between the answer sets of $\Pi$ and the models of its completion. In the following we represent an interpretation in the sense of propositional logic as the set of atoms True in it. With this convention a set of atoms $X$ can denote both an answer set and an interpretation.

If $A_0$ is an atom or the symbol $\bot$, the completion of $\Pi$ relative to $A_0$ is the formula

$$A_0 \equiv \bigvee(A_1 \land \cdots \land A_m \land \lnot A_{m+1} \land \cdots \land \lnot A_n)$$

where the disjunction extends over all rules (1) in $\Pi$ with head $A_0$. The completion $\text{Comp}(\Pi)$ of $\Pi$ consists of the formulas $\text{Comp}(\Pi, A_0)$, one for each symbol $A_0$ in $P \cup \{\bot\}$.

It is well known that if $X$ is an answer set of $\Pi$ then $X$ satisfies $\text{Comp}(\Pi)$ while the converse is not necessarily true. Lin and Zhao (2002) proved that to have a one-to-one correspondence between the answer sets of $\Pi$ and the models of its completion we have to consider the loop formulas of $\Pi$. To state this formally we need the following definitions.

The dependency graph of a program $\Pi$ is the directed graph $G$ such that the vertexes of $G$ are the atoms in $\Pi$, and $G$ has an edge from $A_0$ to $A_1, \ldots, A_m$ for each rule (1) in $\Pi$ with $A_0 \neq \bot$. A loop of $\Pi$ is a set $L$ of atoms such that for each pair $A, A'$ of atoms in $L$ there is a path from $A$ to $A'$ in the dependency graph of $\Pi$ whose intermediate nodes belong to $L$.

Given a loop $L$, we define $R(L)$ to be the set of formulas

$$A_1 \land \cdots \land A_m \land \lnot A_{m+1} \land \cdots \land \lnot A_n$$

for all rules (1) in $\Pi$, with $A_0 \in L$ and $\{A_1, \ldots, A_m\} \cap L = \emptyset$. The loop formula associated with $L$ is

$$\bigvee L \supset \bigvee R(L)$$

where $\bigvee L$ denotes the disjunction of the elements in $L$, and similarly for $\bigvee R(L)$. For instance, the only loop formula of the program $\{p \leftarrow p, p \leftarrow \lnot q\}$ is $p \supset \lnot q$.

**Proposition 1** (Lin & Zhao 2002) Let $\Pi$ be a program, $\text{Comp}(\Pi)$ its completion, and $\text{LF}(\Pi)$ be the set of loop formulas associated with the loops in $\Pi$. For each set of atoms $X$, $X$ is an answer set of $\Pi$ iff $X$ is a model of $\text{Comp}(\Pi) \cup \text{LF}(\Pi)$.

**SAT-Based Answer Set Solvers**

Consider a program $\Pi$. Given Proposition 1 it is clear that if the dependency graph of $\Pi$ has no cycles (in this case we say that $\Pi$ is tight) then the models of $\text{Comp}(\Pi)$ are also answer sets of $\Pi$. Thus for tight programs answer set systems can use SAT solvers as “black-box” search engines. CMODEL used this approach to compute answer sets for tight programs.

If $\Pi$ is non tight, Lin and Zhao (2002) presented the following procedure $LZ(\Pi)$ which still uses SAT solver as black-boxes:

1. Compute $\text{Comp}(\Pi)$ and convert it to a set of clauses $\Gamma$.
2. Find a model $X$ of $\Gamma$ by using a SAT solver. Exit with failure if no such model exists.
3. Compute the set of atoms $X$ such that $\text{Comp}(\Pi) \cup \text{LF}(\Pi)$ is a model of $X$.
4. If $X = \emptyset$, then return $X$.
5. Otherwise, add the clauses corresponding to the loop formulas of all the maximal (under subset inclusion) loops in $X$ to $\Gamma$, and go to step 2.

$LZ(\Pi)$ either returns an answer set for $\Pi$, or failure if $\Pi$ does not have answer sets. In their article Lin and Zhao showed that ASSAT, a system implementing the above procedure, can outperform rival systems often by orders of magnitude. Still, $LZ(\Pi)$ has the following two drawbacks:

1. It is not guaranteed to work in polynomial space. In fact, $\Pi$ can have exponentially many loops: If we assume that each loop formula is not redundant (i.e., that it is not entailed by the rest of the formula under consideration), then
   - If $\Pi$ has an answer set then $LZ(\Pi)$ blows up in space in the worst case, while
   - If $\Pi$ has no answer set then $LZ(\Pi)$ is bound to blow up in space: In $LZ(\Pi)$ adding and keeping loop formulas is essential to guarantee that the SAT solver does not return previously computed models, and ultimately to guarantee ASSAT termination.

2. Considering two successive calls of the SAT solver, the computation done for finding the first model is completely discarded. Thus some branches of the search tree may get computed many times.

These drawbacks can be eliminated if we do not use a SAT solver as a black-box. Instead we can take advantage that state-of-the-art complete SAT solvers are based on the Davis-Logemann-Loveland procedure (DLL) (1962). The basic observation is that DLL can easily work as a SAT enumerator. We can thus compute $\text{Comp}(\Pi)$ and then

- generate models of $\text{Comp}(\Pi)$, and
DLL(Γ, S)
if Γ = ∅ then return True;
if ∅ ∈ Γ then return False;
if {l} ∈ Γ then return DLL(assign(l, Γ), S ∪ {l});
A := an atom occurring in Γ;
return DLL(assign(A, Γ), S ∪ {A}) or
DLL(assign(¬A, Γ), S ∪ {¬A}).

Figure 1: The DPLL procedure

- test whether the generated models are answer sets of II.

Consider DLL as in Figure 1, where l denotes a literal; Γ a set of clauses; S an assignment, i.e. a consistent set of literals. Given an atom A, assign(A, Γ) is the set of clauses obtained from Γ by removing the clauses to which A belongs, and by removing ¬A from the other clauses in Γ. assign(¬A, Γ) is defined similarly. In the initial call to DLL I is the set of clauses of which we compute a model and S is the empty set. DLL(Γ, ∅) returns True whenever Γ is satisfiable, and False otherwise.

Given DLL, we can obtain a SAT-based answer set generator for II by

1. Modifying the first line of DLL in the figure by substituting "return True" with "return test(S, II)", a new function which
   - prints the set atoms(S) = S ∩ P and returns True, if atoms(S) is an answer set of II, and
   - returns False, otherwise.

2. Defining a function ASP-SAT(II), that calls DLL(Γ, ∅) where Γ is a set of clauses corresponding to Comp(II). Γ can be computed in many ways. Here, our only assumptions are that (i) Γ signature extends P, and (ii) for each set X of atoms in Γ signature, X satisfies Γ iff X ∩ P satisfies Comp(II). Standard conversion methods satisfy such conditions.

Notice that the set S in test(S, II) may be non maximal wrt P, i.e., for some atom A in P, both A and ¬A may not belong to S. Thus, S ∪ {A} entails Comp(II) and in principle we also need to check if atoms(S ∪ {A}) is an answer set of II. However, this additional check is not needed, as established by the following proposition.

Proposition 2 Let II be a program, X, X' be two sets of atoms satisfying Comp(II). If X ⊂ X' then X' is not an answer set.

From the above proposition, and the fact that each answer set is also a model of Comp(II) it follows the correctness and completeness of ASP-SAT(II).

Proposition 3 Given a program II, ASP-SAT(II) returns True if and only if II has an answer set.

Moreover ASP-SAT(II) (i) performs the search on Comp(II) and thus does not introduce any extra variables except for those eventually needed by the clause form transformation; (ii) is guaranteed to work in polynomial space; (iii) can deal with both tight and non tight programs. Further,

- In the case of tight problems each generated model of Comp(II) corresponds to an answer set and thus ASP-SAT(II) behaves as a standard SAT solver run on Comp(II).

- ASP-SAT(II) can be easily modified for printing all the answer sets of II: It is enough to modify test(S, II) in order to return False also when atoms(S) is an answer set.

Compared to ASSAT, ASP-SAT is guaranteed to work in polynomial space and no computation is ever repeated, also when computing all answer sets. Compared to other answer set solvers like SMODELS and DLV, ASP-SAT has the advantage of being SAT-based and thus it can leverage on the great amount of knowledge available in SAT.

Still, most of the state-of-the-art SAT solvers based on DLL, e.g. MCHAFF (Moskewicz et al. 2001), use learning when backtracking. With learning, whenever False is returned, a “reason” for the failure has to be computed. Intuitively, a reason is a subset S' of the assignment S such that any assignment extending S' will fail. In order to use SAT solvers with learning, it is thus not enough for test(S, II) to return False when S is not an answer set. Indeed, it has also to compute a reason for such failure, i.e., a subset S' of S such that for any maximal assignment S'' (i) extending S' and (ii) entailing Comp(II), atoms(S'') is not an answer set of II. One such set is S itself. However in order to try to maximize the advantages of learning, it is important that S' be as small as possible. Thus, for computing such S', the test(S, II) procedure

1. computes the loop formulas associated with the loops in atoms(S) – Cons(IIatoms(S)),
2. determines a subset of S which falsifies one of the loop formulas computed in the previous step.

In our experiments, with such a simple procedure, we are able to compute reasons which are often less than 1% of the size of S. Of course, the above method for computing reasons, cannot be applied when returning False because the goal is to determine all the answer sets and atoms(S) is an answer set. In this case, by Proposition 2, the set atoms(S) can work as reason.

In the SAT literature, it is well known that learning can produce exponential speed-ups. We now show that ASP-SAT with learning and the method for computing reasons based on loop formulas, may invoke test(S, II) exponentially fewer times than ASP-SAT without learning.

Assume the program II consists of the two rules2

\[ A_i \leftarrow A_{i+1} \quad A_{i+1} \leftarrow A_i \]

for each \( i \in \{0, 2, \ldots, 2k\} \). Then Comp(II) includes \( A_i \equiv A_i \) (\( i \in \{0, 2, \ldots, 2k\} \)) and we can assume that its classification \( \Gamma \) consists of the two clauses \((\neg A_i \lor A_{i+1}),(A_i \lor \neg A_{i+1})\), for each \( i \in \{0, 2, \ldots, 2k\} \). \( \Gamma \) has \( 2^k \) models while the only answer set of II is the empty set:

\[ 2^k \text{ models while the only answer set of II is the empty set:} \]
• ASP-SAT without learning or with learning but in which \( test(S, \Pi) \) computes \( atoms(S) \) as reason when \( S \) is not an answer set, may generate \( 2 \) \(^k \) assignments entailing \( Comp(\Pi) \).

• ASP-SAT with learning and in which \( test(S, \Pi) \) computes as reason the subset of \( S \) falsifying one of the loop formulas in \( atoms(S) - Cons(\Pi \cup \{ atoms(S) \}) \), may generate at most \( k \) assignments entailing \( Comp(\Pi) \).

Still, for such a simple program, the generation and testing of \( k \) assignments seems an overkill. Indeed, for programs \( \Pi \) without negation as failure, we know that there exists exactly one answer set, \( Cons(\Pi) \). For such programs, ASP-SAT can be easily tuned to directly compute such answer set by first assigning the atoms in \( P \) to \textit{False} while branching. It can be proved that with this modification and for programs \( \Pi \) without negation as failure, the first invocation to \( test(S, \Pi) \) has \( S = Cons(\Pi) \).

### Integration in CMODELS

ASP-SAT was implemented on top of the SIMO system (Giunchiglia, Maratea, & Tacchella 2003) and integrated in CMODELS (Lierler & Maratea 2004) by the last two authors. SIMO is a MCHAFF-like SAT solver (Moskewicz et al. 2001), and features two-literal watching data structure, 1-UIP learning, and VSIDS heuristics. However, it does not feature the low level optimizations of MCHAFF and thus it is within a factor of 3 slower than MCHAFF. Our implementation of ASP-SAT incorporates all the techniques presented in previous section, including the idea to assign atoms first to \textit{False} while branching.

Still, the integration of ASP-SAT in CMODELS posed some challenges related to CMODELS expressivity. CMODELS uses LPARSE as frontend and thus its input may contain cardinality expressions (also called “constraint literals” in LPARSE manual)\(^3\) and choice rules, two constructs widely used in answer set programming.\(^4\) Operationally, CMODELS performs the following steps:

1. Simplifies the given LPARSE program performing preprocessing similar to those involved in SMODELS.
2. Eliminates cardinality expressions by introducing auxiliary atoms and rules. Eliminates choice rules in favor of nested expressions in the sense of (Lifschitz, Tang, & Turner 1999). This is done using a procedure defined in (Ferraris & Lifschitz 2003).
3. Verifies that the resulting program with nested expressions is tight: the definition of tightness is generalized to such programs in (Erđem & Lifschitz 2003).
4. Forms the program’s completion (see (Lloyd & Topor 1984) for the definition of completion of a program with nested expressions) and calls a SAT solver.

For CMODELS, the integration implied calling ASP-SAT instead of the SAT solver. As for ASP-SAT we had to take into account that programs with nested expressions do not satisfy Proposition 2. For instance, the program

\[
A \leftarrow \neg \neg A
\]

(corresponding to the translation of the choice rule “\( \{A\} \)”) has two answer sets: \( \emptyset, \{A\} \). The violation of Proposition 2 led to two modifications in our procedure. Consider a program with nested expressions \( \Pi \). When we are interested in computing all solutions, we have to guarantee that each set \( S \) of literals in \( test(S, \Pi) \) is maximal. Assuming that the input set of clauses is satisfiable, SIMO always returns maximal assignments but in the signature of the set of clauses resulting after SIMO preprocessing. However, SIMO removes tautological clauses in the preprocessing. Tautological clauses can naturally arise during the completion process and removing them may cause the generation of non-maximal (wrt the signature of the input program) assignments. By Proposition 2, this is not a problem if \( S \) does not have nested expressions; it may be a problem otherwise. For instance, the completion of the program (2) is \( A \equiv \neg \neg A \). \( (A \lor \neg A) \) is the tautological clause corresponding to this completion. After the preprocessing, the set of clauses corresponding to the program is empty, and ASP-SAT would not find the answer set \( \{A\} \). Therefore, we modified ASP-SAT preprocessing in order to keep tautological clauses. The second modification involved the function \( test(S, \Pi) \). It considers loop formulas as defined in (Lee & Lifschitz 2003) for nested programs. In the case \( atoms(S) \) is an answer set and we are interested in finding all answer sets of \( \Pi \), \( test(S, \Pi) \) returns the entire set \( S \) as a reasoning since any superset or subset of the atoms in \( S \) may be an answer set of \( \Pi \).

### Experimental Results

CMODELS2 was comparatively tested against other state-of-the-art systems on a variety of benchmarks. Some of the benchmarks we considered include cardinality constraints and choice rules, and will be called “extended”. The systems we considered are SMODELS version 2.27, ASSAT version 1.52 running MCHAFF as SAT solver, DLV release of 2003-05-16. It worths remarking that while SMODELS, ASSAT and CMODELS use LPARSE as preprocessor, and thus can be run on the same problems, DLV does not. This explains why DLV appears only in few tables. Further, ASSAT cannot deal with extended programs. Finally, for DLV we have to mention that it is a system specifically designed for disjunctive logic programs, and that very different results can be obtained depending on the specific encoding being used.

All the tests were run on a Pentium IV PC, with 1.8GHz processor, 512MB RAM DDR 266MHz, running Linux. For SMODELS, ASSAT and CMODELS2, the time taken by LPARSE is not counted.\(^5\) Further, each system was stopped after 3600 seconds of CPU time on an instance, or when it exceeded all the available memory: In the tables, these cases

\(^3\)http://www.tcs.hut.fi/Software/smodels/lparse.ps.gz

\(^4\)The input can also contain general weight expressions (“weight literals”) However, optimize statements (see LPARSE manual) are not allowed.

\(^5\)Adding the times of LPARSE will not change the picture for DLV when compared to CMODELS2.

Table 1: Blocks world: “#b” is the number of blocks.

are denoted with “TIME” and “MEM” respectively. Otherwise, the tables report the CPU times in seconds needed by each solver to solve the problem, or a “—” to denote an abnormal exit of the program.

We start our analysis considering blocks world planning problems, encoded as both standard and extended logic programs, the latter formulation due to Erdem (2002). The results are represented in Table 1. In the table, (i) the column “#b” represents the number of blocks; (ii) an “#” in the “#s” (standing for “number of steps”) column means that the instance corresponds to the problem of finding a plan in “#” steps, where “i” is the minimum integer for which a plan exists. Thus, the instances with “#” and “# + 1” in the “#s” column admit at least one answer set, while those with “# – 1” do not have answer sets. These blocks world problems are tight on their completion models (Babovich, Erdem, & Lifschitz 2000), and thus every model of the completion corresponds to an answer set. As it could be expected, SAT-based systems like ASSAT and CMODELS2 perform (sometimes significantly) better than SMODELS, both on standard and extended programs. On standard programs ASSAT performs slightly better than CMODELS2, and this corresponds to the fact that, on average, MCHAFF is better than SIMO.

We also considered Hamiltonian circuit problems on complete graphs, using both the standard encoding of Niemela (1999), and the extended encoding in the “benchmark problems for answer set programming systems”6. These problems are particularly interesting because they are non tight and have exponentially many loops. Thus, one would expect these problems to be difficult for ASSAT, but also for CMODELS2 in the case it will generate and then reject (exponentially) many candidate answer sets. The results are in Table 2. As can be observed, on this test set CMODELS2 performs best, being faster (sometimes by orders of magnitude) than all the other solvers both on standard and extended programs.

The problems in Table 3 are real-world non tight problem related to checking requirements in a deterministic automaton, and are described in (Ștefănescu, Esparza, & Muscholl 2003).7 Two types of problems are considered and encoded in logic programs. The first type is called IFDD and the results on such problems are reported in the first two rows of the table. The second type of problem is called "Morin", and the results are shown on the last three rows. As can be seen,

Table 3: Checking requirements in a deterministic automaton. DLV was not run on the last 3 instances.

CMODELS2 times out on one instance that is easily solved by all the other solvers. This is due to the dimension of the related propositional formula. On the other hand, for any other solver, there are one/two instances on which CMODELS is at least 1 order of magnitude faster. Interestingly, ASSAT blows up in memory on one instance (and also on other instances, on which the other systems timeout).

Non tight, extended real-world problems corresponding to the bounded model checking (BMC) of asynchronous concurrent systems (see (Heljanko & Niemelä 2003))8 are shown in Table 4. As for the blocks world, these problems are about proving a certain property in a given number of steps, represented as the last number in the instance name. The problems in the first five rows do not have answer sets, while the remaining (obtained by incrementing the number of steps) do. Here the results are mixed, and sometimes CMODELS2 performs much worse than SMODELS. On these problems, our standard heuristic is not well suited. Given a program II, by changing the heuristic in order to

- first assign the atoms occurring within the negation as failure operator, the order and sign of such atoms determined as in SIMO, and
- then assign the remaining atoms first to False, the order determined as in SIMO,

we get the better figures represented in the last column, under the label CMODELS*. The idea behind this heuristic is that we should first get to a set of clauses corresponding to a program II without negation as failure, and then we should try to satisfy the remaining set of clauses by assigning the fewest possible atoms to true.

Summing up, the 4 tables show the performances on 45 problems. If for the Table 4 we consider the results in the

8http://www.tcs.hut.fi/˜kepa/experiments/boundsmodels/
times out on 1 problem, while the other systems do not conclude on at least 3 problems;

- performs better than all the three solvers on 30 problems, and on 26 it has at least a factor of 2; and,

- except for the problem on which it times out, CMODELS2 is either the top performer or within a factor of 2 from it.

We also considered the problem of generating all the answer sets. Here the results are less in favor to CMODELS2 when compared to SMODELS, especially on extended programs. We believe this is because of the very naive way in which reasons are computed by test(S, II), especially when atoms(S) is an answer set.

### Conclusions

We have presented a SAT-based procedure that (i) can deal with any logic program (ii) works on a SAT formula without additional variables, (iii) is guaranteed to work in polynomial space. Further, we have evidenced that ASP-SAT can be easily modified in order to generate all the answer sets. We have shown how to implement ASP-SAT on top of a MCHAFF-like solver, and discussed the modifications needed in the case of extended programs. The experimental evaluation shows that CMODELS2, can have a significant edge over other state-of-the-art systems. Still, we believe that there is a lot of space for improvements, especially in the heuristics, and in the way reasons are computed.

Finally, we believe that ASP-SAT helps in closing the algorithmic gap between answer set and SAT solvers, with beneficial results especially for the former, given the very advanced state of development of the latter.
