Factors associated with reporting of sexual assault among college and non-college women

Ryan Spohn, Abby Bjornsen and Emily M. Wright

Ryan Spohn is the Director – Nebraska Center for Justice Research, Abby Bjornsen is an Assistant Professor and Emily M. Wright is a Professor, all at the University of Nebraska at Omaha, Omaha, Nebraska, USA.

Abstract

Purpose – The purpose of this paper is to examine factors impacting college and non-college women reporting sexual assault to police. The goal is to increase knowledge regarding differences in the rates of reporting and reasons for reporting across these two groups.

Design/methodology/approach – Participants were drawn from a national telephone survey of US women and a sample of US college women. Bivariate and multivariate analyses were conducted to determine factors influencing the reporting of sexual assault to police.

Findings – Non-college women were more likely than college women to report to police. Women who perceived their victimization as rape were much more likely to report to the police and women who had contact with a helping agency were also much more likely to report their assault. Contacting a helping agency is more relevant to non-college women’s reporting to police, while considering the assault a rape is more important for college women.

Practical implications – The results suggest that significant work is needed to encourage women in college to view sexual assaults as worthy of reporting. Boosting victim awareness and access to services is paramount. Providing education and empowerment to student victims to inform their perceptions about the definition of rape is vital, as women perceiving sexual assault as rape are more likely to report the incident.

Originality/value – The research significantly adds to the literature indicating differences in rates of reporting and the factors that impact reporting uniquely for college vs non-college women.

Paper type Research paper

Sexual assault is a pervasive public health and safety issue for women in the USA. Although the risk of sexual assault is present for women at any life stage, women in college (typically between the ages of 18-24 years) have particularly high rates of sexual assault (Fisher et al., 1998). There may be unique risk and lifestyle factors – such as excessive drinking and risky sexual behavior – for women in college, which may increase their risk of sexual victimization (Fisher et al., 1998, 2000). According to the Rape, Abuse, and Incest National Network (RAINN) (2016), women between the ages of 18-24 years are at an increased risk for sexual violence. When compared with statistics for sexual violence for all women collectively, 18-24-year-old women in college are three times more likely to experience sexual violence, and 18-24-year-old women not in college are four times more likely to experience sexual violence.
Despite their higher risk of sexual assault, however, college women are less likely to report the incident to the police (RAINN, 2016; Sinozich and Langton, 2014; Wolitzky-Taylor, Resnick, McCauley, Amstadter, Kilpatrick and Ruggiero, 2011). According to the National Crime Victimization Survey, among females ages 18-24 years, approximately 32 percent of non-students report sexual assault victimization compared to 20 percent of college students (RAINN, 2016; Sinozich and Langton, 2014). This discrepancy exists even though the percent of sexual assaults involving an acquaintance and involving a weapon are the same between the two groups (Sinozich and Langton, 2014). There are several reasons why victims of sexual assault fail to report the incident to the police. According to recent statistics for women ages 18-24 years, 26 percent of students and 23 percent of non-students believed it to be a personal matter and 20 percent of both students and non-students feared reprisal. Moreover, 12 percent of students and 19 percent of non-students believed their victimization was not important enough to report, 10 percent of students and 14 percent of non-students did not want to get their perpetrator in trouble, and 9 percent of students and 10 percent of non-students believed the police would not or could not do anything to help (RAINN, 2016; also see Fisher et al., 2000).

Institutions of higher education offer supports and resources for students impacted by sexual assault that may be unavailable for most non-college victims (e.g. women’s centers, campus counseling centers, etc.). However, these resources do not result in higher rates of service utilization. Among 18-24-year-old females, only 16 percent receive assistance from victim service agencies (RAINN, 2016). Comparisons of reporting behaviors between college and non-college women are rare. The purpose of this study is to examine factors that influence the likelihood that sexual assault victims report the incident to the police, paying special attention to the roles of perceptions of sexual assault and contact with other helping agencies among college and non-college women.

**Factors related to reporting sexual assaults among victims**

Given the pervasiveness of sexual assault among young women, researchers have investigated reporting practices, as well as factors that may influence the decision to report the assault to authorities. Reporting a sexual assault typically entails notifying police, campus authorities, or community agencies established to assist victims (Orchowski et al., 2009). It is important to understand the reasons for reporting or not reporting sexual assault events since higher rates of reporting can reduce the likelihood that offenders can repeat their crimes, and increase the likelihood that victims will receive needed services (Orchowski et al., 2009).

Unfortunately, much sexual assault goes unreported to police, regardless of college status. According to the National Violence Against Women Survey (NVAWS), less than 20 percent of sexual assaults are reported to law enforcement (Tjaden and Thoennes, 2006). In their meta-analysis, Sabina and Ho (2014) found that rates of reporting sexual assault to police were uniformly low across studies (less than 13 percent). In another investigation using NVAWS data, Tjaden and Thoennes (2006) found that only 19 percent of sexual assaults were reported to police, and that the reporter was oftentimes a family member or friend of the victim rather than the victim.

Several factors impact the likelihood of reporting a sexual assault to authorities. Sexual assaults are more likely to be reported to the police when they are more severe in nature, such as those involving weapons, physical force, or injury (Sabina and Ho, 2014; Wolitzky-Taylor, Resnick,
Amstadter, McCauley, Ruggiero and Kilpatrick, 2011), when the perpetrator is a stranger (Fisher et al., 2003; Suzuki and Bonner, 2017), when the victim has a better memory of the event (Kilpatrick et al., 2007), and when the victim was not under the influence of substances (Kilpatrick et al., 2007; Krebs et al., 2007; Wolitzky-Taylor, Resnick, Amstadter, McCauley, Ruggiero and Kilpatrick, 2011). Additionally, victims who are seeking justice, who trust police and university officials, or desire services (e.g. physical exams and testing for disease, see Moore and Baker, forthcoming) are more likely to report the assault. Conversely, women with a history of sexual victimization are less likely to report to the police, and those who do report are more likely to tell to a friend or family member than a community agency or the police (Fisher et al., 2003; Orchowski et al., 2009; Schulze and Perkins, 2017; Tjaden and Thoennes, 2006; Wolitzky-Taylor, Resnick, Amstadter, McCauley, Ruggiero and Kilpatrick, 2011). Existing research on college women indicates that demographic characteristics such as age, race/ethnicity, year in school, and income are unrelated to help-seeking among sexual assault victims (Amstadter et al., 2010).

Uncertainty and confusion as to whether or not the sexual assault qualified as a crime serves as an additional barrier to reporting, as do fears that police will not perceive the assault to warrant reporting (Sabina and Ho, 2014). Myths about sexual assault also impact reporting behaviors (Orchowski et al., 2013). For example, the belief that sexual assault is a crime typically perpetrated by strangers often results in victims of acquaintance rape believing that they will be held responsible for the incident, or that they will be blamed for their assault (Bridges and McGrail, 1989; Dupuis and Clay, 2013; Grubb and Harrower, 2009; Lea, 2007). Similarly, women assumed by others to be sexually promiscuous often receive the message that they may be blamed for their assault should they choose to report (Cohn et al., 2009; Heaven et al., 1998; Luginbuhl and Mullin, 1981). Women consuming alcohol or other substances prior to or during their victimization often fear that their sexual assault will not be classified as a crime since they were under the influence of perception-altering substances (Littleton and Axsom, 2003; Littleton et al., 2006, 2008, 2009; Stormo et al., 1997). Relevant to the current study, all of these factors may influence the likelihood that a victim perceives the assault to be serious enough to warrant police intervention (i.e. reporting).

In fact, the most impactful barrier in reporting sexual assaults to police may be the victim’s perception that the assault is not serious enough to report (Sabina and Ho, 2014), which may be influenced by some of the above factors. To demonstrate, Orchowski et al. (2013) found that only 21 percent of assaulted women labeled their experience as sexual assault or as a crime, and Walsh et al. (2016) found much fewer women who labeled their sexual assault as rape when drugs or alcohol was involved (24 percent) vs when force was involved (73 percent). Several of the factors reviewed above that are associated with reporting of sexual victimization may be especially relevant to women in college, and thus may partially explain the lower likelihood of reporting behaviors among this group. Given their different circumstances, additional research is needed to examine differences between college and non-college victims in their perceptions of sexual assault as rape, as well as the impact of perceptions on likelihood of reporting.

**Current study**

This study examines the factors that influence sexual assault reporting among female victims of sexual assault. Bivariate differences were assessed across two variables: educational status (college vs non-college women) and perception as rape (women who perceived their sexual assault as rape vs women who did not). A multivariate regression model was then used to identify the factors that predict whether or not victims reported the assault to police. Due to sample size...
limitations, it was not possible to examine this question in separate regression models among college and non-college women.

Method

Participants

Data from two sources were utilized to ensure adequate samples of college and non-college female victims of sexual assault. One group was part of a national telephone household sample of 3,001 US women, and the other group consisted of 2,000 college women selected from a reasonably representative national list of women attending four-year colleges and universities in the USA. Interview protocols were identical across both data sources. Data collection for both samples occurred in 2006.

The first group originated from a national cross-section of 2,000 women aged 18-34 years plus a national cross-section of 1,000 women aged 35 years and older. Researchers used random-digital-dial methodology for selecting these samples, which were geographically stratified (Kilpatrick et al., 2007) to ensure that regional distributions were proportionate to regional populations. This group included 218 women, 30 of whom were in college at the time they were interviewed. Due to the focus on differences across college and non-college women, the subsample was limited to women whose age of most recent or only victimization was between the ages of 17 and 23 years (the typical age of college students in the USA).

The second group originated from a sample of 2,000 college women recruited using the American Student List: the largest and most widely used list of college students in the USA (Kilpatrick et al., 2007). The sample was divided into nine geographic regions, and women were contacted in proportion to the US Census representation of the population of college women in each region (Paul et al., 2013). Women ages 18 years and over were interviewed using a computer-assisted telephone interviewing system. The sampling frame contained approximately 17,000 individuals, and was restricted to women attending four-year public and private institutions of higher education. Women were sampled from 253 different colleges and universities in 47 different states (73.5 percent response rate, Kilpatrick et al., 2007). The original sample included 2,001 survey respondents. The sample analyzed in the current study included 146 women. The age of most recent or only victimization for these women was between the ages of 17 and 23 years. The total sample analyzed for the current study included 364 women, 176 of whom were enrolled in college at the time interview, and all of whom experienced sexual victimization during the ages of 17 and 23 years. The primary strength of this data is that all respondents answered the exact same questions, providing an optimal opportunity for comparing rates of reporting and reasons for reporting across college vs non-college women.

Measures

Survey respondents provided information about their age, ethnicity (Hispanic/Latino ¼ 1, otherwise 0), race (non-white ¼ 1, white ¼ 0), whether they were ever married (never married ¼ 1, otherwise 0), level of education (eighth grade ¼ 1, some high school ¼ 2, high school graduate ¼ 3, some college ¼ 4, four-year college graduate ¼ 5, some graduate school ¼ 6, and graduate degree ¼ 7), and household income (ranges from 1 to 8, where 1 ¼ less than $10,000 and 8 ¼ $200,000 or more). If respondents were in college, they were asked to provide an estimate of their parents’ or primary guardians’ total household income in lieu of their own household income.

Rape was defined as penetration of the victim’s vagina, mouth, or rectum without consent. If a
respondent reported experiencing more than one victimization, she was asked to provide information relative to her most recent victimization. The data include a number of characteristics of the victimization that have been linked to reporting in the literature (Crawford et al., 2008; Kimble et al., 2008; Loughnan et al., 2013; Maurer and Robinson, 2008; McCauley and Calhoun, 2008; Mohler-Kuo et al., 2004). For example, respondents were asked if the perpetrator used force or threat of force, if the offender was an acquaintance, and if they were under the influence of drugs and/or alcohol at the time of the victimization (all dichotomous measures). Respondents provided information about previous sexual victimization (yes ¼ 1, no ¼ 0), age at the time of the victimization, contact with an agency that provides assistance to victims (yes ¼ 1, no ¼ 0), and remembering details of the event (not well at all ¼ 1, not so well ¼ 2, very well ¼ 3, and extremely well ¼ 4). The measure of vicarious victimization reflects an affirmative response to the question: “Has a woman or girl ever directly told you that someone forced her to have sexual intercourse, oral sex, or anal sex when she didn’t want to?”

The current study aims to address the literature gap relative to the impact of victim perceptions of sexual assault on reporting behaviors. Participants responded to the following question: “Looking back on what happened, which best describes how you felt about the incident?” Respondents who perceived the incident as a rape were coded “1” on this variable, while respondents who perceived the incident as some type of crime but not a rape, an unpleasant incident but not a crime, or “not sure” were coded “0.”

The dependent variable reflects whether or not the respondent or someone else reported the incident to the police (1 ¼ reported; 0 ¼ not reported). Additional information on the operationalization of all variables is available upon request to the lead author.

Results

Descriptive statistics

Descriptive statistics are displayed in Table I. Approximately 17 percent of respondents stated that they had sought help from an agency. Approximately 42 percent of women perceived the assault to be a rape. Only 13 percent of respondents indicated that police were contacted regarding the victimization in question.

Bivariate analyses

Differences between college and non-college victims. Table I includes the results of χ² tests and independent samples t-tests to compare mean differences between college vs non-college victims.

Non-college victims were more likely to experience perpetrator force during their assault. College victims were more likely to be under the influence of alcohol or drugs at the time of their assault, and were more likely to have experienced previous victimization. Perceptions of victimization varied between college and non-college women in the sample. Over 50 percent of non-college women perceived their victimization as rape, whereas only 31.8 percent of college women perceived their victimization as rape. Almost twice as many non-college victims reported their victimization to the police (17.6 percent) as compared to the college victims (9.1 percent).

Perceiving victimization as rape. Respondents perceiving their incident as rape were older, had a lower household income, were less likely to be in college, and less likely to be never married (Table I). In cases where perpetrator force was used, respondents were more than 30 percent
more likely to perceive the assault as rape. Victims who were under the influence at the time of the assault were significantly less likely to perceive the assault as rape. Respondents were more likely to perceive the assault as rape if they had been previously victimized, experienced vicarious victimization, had sought the help of an agency, and if they reported a better memory of the incident. Importantly, victims perceiving their assault as rape were more than six times more likely to report their assault to the police.

Multivariate analyses

Predictors of reporting to police. As demonstrated in Table II, women who were in college at the time of the assault were more than four times less likely to report their victimization to the police \((\exp(\beta) \approx 0.239)\). None of the characteristics of the victimization impacted reporting to police at a 0.05 level of significance. However, women who sought help from an agency such as a rape crisis center were more than five times more likely to call the police \((\exp(\beta) \approx 5.182)\). Finally, victims perceiving the assault as rape were about six times more likely to report to police \((\exp(\beta) \approx 5.709)\).

Because the effects of college attendance, perceptions that the assault was a rape, and contacting a help agency were strongly related to reporting to police, we further explored perceptions, help-seeking, and reporting among college and non-college women, separately, using \(\chi^2\) analyses (not shown). We found that force was more strongly related to non-college
women’s perceptions of rape than among college women, $\chi^2 (1, n = 187) \approx 29.96^{***}$ and $\chi^2 (1, n = 174) \approx 8.25^{**}$, respectively. Being under the influence at the time of the incident was more relevant to college women’s perceptions that the assault was rape than among non-college women. Additionally, the effect of previous victimization on perceptions that the assault was a rape was more relevant for non-college women, $\chi^2 (1, n = 188) \approx 11.20^{***}$, than college women ($\chi^2$ not significant).

$\chi^2$ analyses were implemented to detect any systematic differences in the reasons why college and non-college women sought help from a service agency (a strong predictor of reporting to the police in our multivariate models), as this would again explain the differing reporting rates across the two groups. Interestingly, being under the influence of substances was equally related to contacting a helping agency among college and non-college women. The effects of prior victimization and use of force, however, were stronger for non-college women’s decisions to contact a helping agency relative to college women (both were non-significant for college women). However, the effect of perceiving the assault a rape was stronger for college women – 33 percent of college women who considered the incident as a rape reached out to a helping agency, compared to 23 percent of non-college women, $\chi^2 (1, n = 176) \approx 15.06^{***}$ vs $\chi^2 (1, n = 187) \approx 7.41^{**}$, respectively.

Finally, in our examination of reporting to the police, most importantly, we found that considering the assault a rape was more influential for college women’s reporting to police than non-college women, $\chi^2 (1, n = 176) \approx 31.17^{***}$ vs $\chi^2 (1, n = 187) \approx 9.36^{**}$, respectively. Finally, 54 percent of non-college women who contacted a helping agency reported the assault to the police, compared to only 22 percent of college women.

**Discussion**

This study extends research exploring factors related to victim’s perceptions of their sexual assault, and factors relating to reporting to police among college and non-college women. Compared to other recent studies (e.g. Orchowski et al., 2013), the sample in the current study exhibited a high rate of perceiving sexual victimization as rape (42 percent). This may be attributed to different definitions of victimization, as the data used in the current study included only sexual assaults that involved penetration (vaginal, anal, or oral). The finding that police were contacted by only 13.5 percent of victims is an important research focus, as higher rates of reporting may reduce the likelihood that offenders can repeat their crimes, increase the likelihood that victims will receive needed
services, and allow researchers to more fully understand the nature of sexual victimization for both college and non-college women.

The current study examined the factors that impact reporting of rape to police. Consistent with prior research (e.g. Sinozich and Langton, 2014), we found that non-college women were more likely to report to police than college women. Women who perceived their victimization as rape were nearly six times more likely to report to the police. Moreover, women who had contact with a helping agency were over five times more likely to report to the police. When disaggregated by college vs non-college subsamples, we found that the effect of contacting a helping agency is more relevant to non-college women’s reporting to police, while considering the assault a rape is more important to college women.

Our results point to important policy implications, particularly on college campuses. The rate of classifying experience(s) of sexual victimization as rape was higher (42 percent) than figures found in other studies. Over half of the current sample (58 percent) refrained from labeling their assault as rape, meaning that they were less likely to contact victim service agencies, resulting in lower rates of reporting to authorities. Fewer college women than non-college women perceived the assault as a rape (31 percent vs 51 percent, respectively), and this was partially due to the impact of being under the influence (which had a stronger influence on college women’s views of “rape”). However, considering the assault as a rape was a stronger influence on college women’s likelihood of contacting a helping agency than for non-college women. Only 22 percent of college women who contacted a service agency reported the assault to police, while 54 percent of non-college women who consulted a service agency did so. The pattern of results suggests that considering the assault as a rape is more influential for college women’s reporting behaviors – to helping agencies or the police – than it is for non-college women, while contacting a helping agency is more important to reporting to the police for non-college women. Our results suggest that significant work is needed to encourage women in college to view sexual assaults as worthy of reporting – to anyone (not just the police) – while getting non-college women to contact a helping agency may be more important for this group. The difference is in part because non-college women tend to view the assault as a rape more often than college women.

Boosting victim awareness of and access to services is paramount. For both students and non-students, the accessibility of 24/7 national crisis hotlines are imperative for immediate and confidential access to support. Some national hotlines work closely with local service providers, and can easily connect victims to in-person services in their area (RAINN, 2016).

Public education serves as an additional priority. The findings of this study suggest that providing education and empowerment to student victims to inform their perceptions about the definition of rape is vital, as women perceiving sexual assault as rape are more likely to report the incident. The RAINN (2016) asserts that public education can occur through a variety of mediums, including speakers bureaus, social media, and even depictions on network television. In short, the more exposure young women have to accurate information about sexual assault (e.g. what constitutes sexual assault, current victim and reporting statistics, ways of reporting, etc.), the more likely they are to correctly classify their experience and to seek the assistance they need.

The main limitation of the current study is the risk of making causal inferences from cross-sectional data. The association between victims contacting helping agencies and increased perceptions of rape was interpreted in causal terms in the current study, although it is possible that the relationship operates in the reverse direction, with victims perceiving their assault as a rape being more likely to contact an agency. Future research on the relationships between victim perceptions, rates of victims contacting helping agencies, and rates of reporting to police should examine longitudinal data that ensure correct temporal ordering.
Another limitation is inadequate data on the type of helping agency contacted, and type of services received. For example, for college students who contacted an agency, it is unknown if that agency was affiliated with their college or university. For the purpose of this study, this was assumed to be the case. To fully understand the importance of contacting such agencies, additional data are needed to correctly identify the policies that will encourage the highest rates of reporting. An additional limitation concerns the restricted age range to include only traditional college students (typically between the ages 18-24 years). This age range certainly does not capture or represent all college women (nor their non-college cohorts), and future researchers may wish to broaden the inclusion criteria for age to ensure a more generalizable result. Another limitation is our inability to discern whether the victim or someone else reported the rape to authorities.

As the current research is limited in that it omits male victims of sexual assault, future research should compare factors impacting sexual assault reporting of college and non-college males. We also encourage future research to untangle the complex relationships between perceptions of rape and help-seeking behaviors, such as reporting sexual assaults to police or other agencies, among college and non-college women. It is possible that the supports and resources available on most college campuses (e.g. counseling centers, women's centers, etc.) eliminate the need for women to go directly to police, as the supports available to them function as liaisons with police. It is also likely that non-college women who reach out to a designated agency will receive information about what constitutes rape, which may result in a stronger likelihood of perceiving an assault as rape. Similar to supports on college campuses, staff at agencies in the community typically also serve as liaisons to police, potentially accounting for increases in police reports. Thus, the mechanisms by which college and non-college women seek help in the aftermath of sexual assault may be different.
