Nebraska County Population Projections: 2010 to 2050

Prepared by:
David Drozd, Jerry Deichert
Center for Public Affairs Research
University of Nebraska at Omaha

December 2015

Introduction:

There are many potential uses of understanding how the population might change into the future. Population projections help us to plan and prepare for likely demographic changes. Using the current population structure and applying birth, death, and net migration rates and how they change for various ages provides a glimpse of the changes and shifts that are likely to occur as well as the timing of such changes.

This report presents population projections for each of Nebraska's 93 counties, as well as the state total by summing the 93 county results. The report was supported in part by the Nebraska Legislative Planning Committee.

Description of Data and Methods:

These population projections utilize a variety of data to simulate the real "flow" of the population over time. With each passing year, the population ages one year forward to become one year older. In addition, life events occur including births, deaths, and the movement of people from one location to another. This section describes the data and methods utilized to estimate the population flow from 2010 to 2050 for Nebraska and its counties.

The starting point for the population projections is the 2010 Census results. Single year of age data for both males and females were compiled for each individual county. Then birth, death, and net migration rates were assigned to each single year of age. The rates multiplied by the relevant age data produced the number of births, deaths, and net migration that occurred each year, and the specific ages at which these events occurred. Thus, the population in 2011 took the 2010 values, added births at age 0/under age 1 (with a split of 51% to males and 49% to females per current trends in actual data), subtracted deaths by the single year of age at which they occurred given the rates, and added or subtracted net migration based upon the specific ages of the population and the migration rates that had occurred during the 2000s decade.

County Classification Groups

Many Nebraska counties have relatively small populations. Thus, the number of birth, death, and migration events in these counties are relatively small and can vary widely from year to year. Therefore, to provide more stability and less fluctuation to the data, counties with similar characteristics and migration patterns were grouped, and the rates for the group as a whole were calculated and then applied to the individual counties in that group. This reduced the effect of small numbers and the choppy or erratic nature of working with information from relatively sparsely populated areas in which few life events occur in a given year.

Douglas County containing the city of Omaha and **Lancaster County** containing the city of Lincoln have a large enough population to provide individual projections without any county grouping. Nebraska's 3rd largest county, Sarpy, has a substantially larger population than the next largest county (Hall), and is unique among Nebraska's counties in that its location near Omaha

has led to strong population and housing growth in recent decades. **Sarpy County** had by far the highest level of net immigration during the 2000s, and it occurred for nearly all age groups, a distinct pattern compared to other counties. Thus, it was deemed essential to use Sarpy County's data specifically, and not group it with any other counties.

Certain other Nebraska counties follow Sarpy County's example of relatively strong migration given their proximity to Omaha and Lincoln and commuters who work in these larger cities but reside in the nearby counties. **Cass, Dodge, Gage, Otoe, Saunders, and Washington Counties** border either Douglas or Lancaster County and were found to have similar migration patterns during the 2000s, namely that they had a net outmigration of those at college age (15-29) but had an immigration for those of working age as well as children under 15 (families of the workers moving into these areas). Washington County did have net immigration of those aged 15-19 in the 2000s, but given the closure of Dana College in Blair the migration is likely to soften going forward. **Cheyenne County**, containing Sidney and Cabela's as a major employer, also had this migration pattern during the 2000s and was thus placed into this group of counties that were impacted by jobs or commuting, which will be referred to as "commuter counties".

Other types of counties with unique migration patterns included those with a "major college". **Buffalo, Dawes, and Wayne Counties** were included in this category as each had extremely high migration rates for the 5-year age groups of 15-19 and 20-24, followed by high levels of outmigration for ages 25 to 39. These counties contain the University of Nebraska at Kearney, Chadron State College and Wayne State College respectively.

Similarly, counties with a "small college" were grouped together. **Adams, Nemaha, Saline, and Seward Counties** home to Hastings College, Peru State College, Doane College, and Concordia University were included in this category. They were distinct from the "major colleges" and the "commuter counties" in that they only had a large immigration for the 15-19 five-year age group. Outmigration occurred for the 20-24 age group, and the outmigration was especially high for those who migrated during the 2000s who were aged 25-29 in 2010 (all migration by age values refer to the age of the person at the end of the 2000s period in 2010 – they could have migrated at any point during the 2000s but the movement is summarized for the ending age in 2010).

Nebraska has several counties that contain a city of at least 10,000 persons and serve as regional centers for shopping and services. Two of these counties are defined by the Office of Management and Budget (OMB) as being metropolitan (Hall and Dakota) while the others are classified as being "micropolitan". Counties with a city of 10,000 that were not already classified into another category (e.g. Dodge and Gage as "commuter counties" and Buffalo as a "major college") fell into this category. **Dawson, Lincoln, Madison, Platte, and Scotts Bluff Counties** along with **Hall and Dakota Counties** comprised the "regional centers" category.

The remaining Nebraska counties were primarily rural in nature. In analyzing population changes during the 2000s, it has been noted that counties containing a city of 5,000 residents performed better from a population change standpoint than those that did not have a city of this

size. This stems from both a higher level of natural change (births – deaths) as well as better net migration levels. For example, during the 2000s the “city of 5,000” counties of **Box Butte, Colfax, Phelps, Red Willow, and York** had a net outmigration rate of about 50% for 20-24 year olds. In comparison, the outmigration rate was about 80% for counties rural in nature not containing a city of 5,000 people.

This left 64 Nebraska counties without a larger city or college yet to be classified. Two groups of 32 counties were formed based upon their net migration rates during the 2000s. The level of net migration was found using the difference in the 2000 and 2010 Census counts, accounting for the births and deaths that occurred within the county between the ten calendar years from 2000 to 2009. The migration rate was calculated as the net migration divided by the total population of the county at the start of the period in 2000. The migration rates were ranked and the 32 best counties were placed into a “high migration” group with the other 32 counties falling into a “low migration” group of counties. The cutline between the groups turned out to be a decade migration rate of -6.5% during the 2000s. Overall, the “high migration” rural counties as a group had an outmigration rate of -3.3% versus a -9.3% rate in the “low migration” rural counties. See **Table 1** for a listing of counties and the category into which they were grouped.

Births and Fertility Rates

The number of births by single year age of the mother for each county was obtained from the Nebraska Department of Health and Human Services. Births by single year of age were compiled for calendar years 2008 through 2012. These five years of births were then totaled and averaged for each individual large county (Douglas, Lancaster, Sarpy) or group of counties. The average number of births by single year age of mother were then divided by the 2010 Census count of women for those respective years of age to obtain age specific fertility rates. The rates for individual years of age were then “smoothed” by calculating the rate for three specific ages and centering it on the middle year. For example, the fertility rate for age 23 was the sum of births to 22, 23, and 24 year olds, divided by the number of women aged 22-24. This helped the rates ascend and descend in an orderly fashion, rather than erratically given small numbers of events at the extreme ends of the span of ages during which births occur. Fertility rates were applied to the number of women aged 13 to 49.

Deaths and Survival Rates

Projected survival rates by single year of age and gender were taken from national Census Bureau projections. These rates were then adjusted to be more representative of Nebraska by using a ratio for survival in Nebraska versus the nation, since survival rates are lower across the U.S. than in Nebraska (due to the larger presence of minority population groups nationally that tend to have lower survival rates). The specific set of survival rates from the Census Bureau that were used were called the White non-Hispanic/Asian Pacific Islander series, since Nebraska is predominately White non-Hispanic regarding race and ethnicity. To better track the number of events experienced locally, survival rates for each single year of age were decreased by 0.1% in Douglas County and the “regional center” counties, where minorities comprise a relatively larger share of the local population. Conversely, survival rates were increased by 0.1% for each single

year of age in the “rural high migration” and “rural low migration” categories, since these areas are relatively more White non-Hispanic than other parts of the state.

Net Migration Rates

The rate of net migration for specific five-year age groups during the 2000 to 2010 period was calculated for each county classification group. The rates were calculated by taking the 2000 Census counts by single year of age and subtracting actual deaths by the single year of age at which they occurred. This, when births are included at age 0 in later years, effectively flows the population over time if no net migration had occurred. The difference in the flowed values at the end of the period compared to actual population estimates or census counts indicate the level of migration that was experienced. The rate is found by dividing the net migration by the corresponding cohort population at the start of the period, or 5 years of summed births for the 0-4 age group.

Two sets of rates over 5 years, from the 2000 Census to the Census Bureau’s 2005 population estimate and then from that 2005 estimate to the 2010 Census, were calculated and averaged to provide migration rates for each 5-year age group from 0-4 years to age 85 and older. Using the two sets of 5-year rates is believed to be a more accurate approach for how the population actually changes. This approach follows the migration of the population more closely than simply using one set of deaths and population flows compared only at the end of the timeframe in 2010.

With migration rates by 5-year age groups established, a smoothing procedure was applied to convert the data into single year of age migration rates. This was accomplished mathematically by placing the exact 5-year rate at the center year of the 5-year age group, and then adding or subtracting an appropriate amount per year so that the next 5-year age group was also at its specific rate in the center of the 5-year category. For example, the Douglas County migration rate for 5 to 9 year olds was 0.5%. The rate for 10 to 14 year olds was 2.0%. Thus, seven year olds at the center of the 5 to 9 age group were applied the 0.5% rate and then the rate for each higher single year of age was increased by 0.3% to hit the 2.0% target at age 12. This process was repeated for the other 5-year age groups and their specific migration targets to age 87 for the 85 and older category. Migration rates for ages 88, 89, and 90 were calculated in a linear fashion so that they became a rate of 0 (no migration) at age 90. Migration rates for individual ages above age 90 were held at a rate of 0 (no migration).

One advantage in utilizing migration rates by single year of age is that they allow a more accurate detailing of the large population movement that occurs for college. More urban areas with the colleges experience large inflows of 18 and 19 year olds, while rural areas lose a lot of people at this age as they leave for college. Migration rates are also greatly impacted as people finish or leave college and often move away from college locations, sometimes returning to their hometown.

To account for these large migration shifts at specific college-related ages, a ratio method was used. Starting at age 15, ratios for 15 to 16 year olds, then 16 to 17 year olds, 17 to 18 year olds, etc. were calculated from 2010 Census data. This showed how the population changed in the local area due to the college attendance effect. The ratio analysis was analyzed through age 25 to follow the migration patterns as people finished college. Migration rates that replicated the ratios by single year of age were applied to project the population shifts at these ages properly. Single year migration rates by age 27 were again made into the target 5-year migration rate for 25-29 years olds as described above, since age 27 was the center of this 5-year age group. This detailed process makes the projections better reflect the actual way that populations change at ages that are typically associated with college and associated moves to or from a specific area.

Notes and Discussion:

Population projections will only ever be a guide and as accurate as how well the assumptions that they are based upon hold true into the future. With that in mind, a few items regarding these projections should be made.

Births and Fertility

Births and fertility rates were calculated from the 2008 to 2012 period, an even 5-year interval around the 2010 census counts, which reflected the most accurate number of women at specific ages in each area. Given the economic recession that began nationally in 2007 and more locally in Nebraska in 2008, the level of births and childbearing patterns changed over this period. Nebraska hit a near term high in births during 2008, and then births fell for three straight years from 2009 to 2011 before rebounding somewhat in 2012 as the economic recovery took hold. The decline in births was especially large among the Hispanic population. Thus, certain areas in Nebraska, especially those with a large Hispanic presence, might have a higher level of births going forward than what these projections suggest, since the birth rates utilized are based upon a timeframe in which births were somewhat lower than in other recent years. Conversely, some areas saw little change in the level of births over the 2008 to 2012 timeframe, namely the “major college” counties and the rural county groups. These areas may have been impacted by additional college enrollments when job prospects were relatively low, or from bolstered incomes and their positive effect on births (and migration) when the farm economy and agricultural commodity prices were as historic highs during this period.

Net Migration

Also worth noting are the migration rates which were based solely on the 2000 to 2010 period. During this time Nebraska had some high outmigration years early in the decade, as well some relatively high net immigration years late in the decade, as fewer Nebraskans left the state and a higher number of people came to the state during the recession, presumably for work purposes. When compared to other decades, migration during the 2000s was similar to the 1970s, well above the “farm crisis” years with high outmigration during the 1980s, and well below the “immigration wave” that occurred during the 1990s. Thus, the 2000s period represents an average migration period, or what is often referred to as the “trend” level, since it is based upon

what has occurred most recently. If Nebraska would experience another large outmigration decade like the 1980s, or one with high immigration like the 1990s, these projections would differ to some degree from what is experienced in reality.

These projections also simply assume that birth and migration patterns will stay as they are currently into the future. The projections simply apply the current rates consistently over time. No attempt was made to “predict” what might happen in the future regarding childbearing trends or what is likely to happen regarding future international or domestic migration levels. Trends in family size or the age at which families are formed and births occur could change, and local and national policies could have a large impact on future local and international migration. It is also possible that the rate of migration will become lower as the base population grows over time, but for these projections the migration rates were held steady for each decade. Survival rates based upon Census projections reflect their analysis of how survival at various ages will likely change in the future, namely that survival will continue to improve given medical advances. Thus, expected future changes in survival are accounted for, but only time will tell how accurate those assumptions prove to be.

Effects of Grouping Counties

The assumptions made in these projections were applied to county groupings as a whole, since it was not feasible or accurate to calculate and utilize specific rates for individual counties with small populations. Thus, the migration, birth, or survival rates applied to a specific county based upon the combined data for the entire group of counties may not match what a specific individual county will experience. For example, when calculated specifically, Nemaha County has a relatively low fertility rate of 63 births per thousand women aged 15-44 based upon 2008-2012 average births and the 2010 Census count. It is grouped with the “small college” counties where the combined fertility rate for the group is 70. Thus, due to grouping Nemaha County will be projected to have relatively more births than what it will likely experience going forward.

Likewise, some of the rural “high migration” counties experienced net immigration during the 2000s. However, the migration rate for the 32 counties when combined was an outmigration of 3.3%. Thus, the projections will understate migration for certain counties if they are able to experience net immigration going forward as they did in the recent past. The bottomline is that the projections are designed for the entire group of counties to hit their targeted fertility and migration rates that were experienced recently in actuality, and certain individual counties may have different experiences and trends than the broader group of counties. The projections represent what an individual county will experience if the rates from their peer group hold over time into the future.

Drawing Conclusions from the Data Provided:

The purpose of this report is to provide the projected population data from 2010 to 2050 by age group for Nebraska and each of its 93 counties, and provide a description of how those data were calculated. Thus, each county will have a separate page displaying its data, with a consistent

template being used for display. A set of appendices at the end of the report will provide a summary of the fertility rates and targeted 5-year migration rates for the county groups. It is left to the users of this report to draw their own conclusions from the data provided, and what they mean for Nebraska and its specific counties moving forward.

Table 1. Nebraska Counties Categorized by Similar Characteristics for County Population Projections

Prepared by: Center for Public Affairs Research, UNO

Note: the purposed of these classifications is to group similar counties so that more accurate aggregated birth, death, and net migration rates can be applied consistently to the age structures of the specific counties.

Counties that are relatively densely populated and are not grouped/have their own specific rates (3):

Douglas Lancaster Sarpy

Counties with high levels of commuting/local jobs - "commuter" counties (7):

Cass Cheyenne Dodge Gage Otoe Saunders Washington

Counties that have a city of 10,000 residents and are a "regional center" (7):

Dakota Dawson Hall Lincoln Madison Platte Scotts Bluff

Counties that have a "major college" (3):

Buffalo Dawes Wayne

Counties that have a "small college" (4):

Adams Nemaha Saline Seward

Counties that have a "city of at least 5,000 residents" (5):

Box Butte Colfax Phelps Red Willow York

Counties without a city of 5,000 that had a "relativley high" level of migration in the 2000s (32):

Arthur Butler Chase Custer Deuel Franklin Furnas Garden
Garfield Gosper Greeley Hamilton Harlan Hitchcock Hooker Howard
Jefferson Johnson Keith Kimball Knox Logan McPherson Merrick
Nance Nuckolls Pawnee Perkins Polk Sherman Valley Webster

Counties without a city of 5,000 that had a "relativley low" level of migration in the 2000s (32):

Antelope Banner Blaine Boone Boyd Brown Burt Cedar
Cherry Clay Cuming Dixon Dundy Fillmore Frontier Grant
Hayes Holt Kearney Keya Paha Loup Morrill Pierce Richardson
Rock Sheridan Sioux Stanton Thayer Thomas Thurston Wheeler

Projections for Nebraska Population using 2010 Census as starting point (sum of 93 county projections)

Source: December 2015 Nebraska County Projections, Center for Public Affairs Research, UNO
